

## SQL - Funkcje okna (Window functions) Lab 1

---

**Imiona i nazwiska: Marek Małek, Mateusz Lampert**

---

Celem ćwiczenia jest przygotowanie środowiska pracy, wstępne zapoznanie się z działaniem funkcji okna (window functions) w SQL, analiza wydajności zapytań i porównanie z rozwiązaniami przy wykorzystaniu “tradycyjnych” konstrukcji SQL

Swoje odpowiedzi wpisuj w miejsca oznaczone jako:

---

Wyniki:

-- ...

---

Ważne/wymagane są komentarze.

Zamieść kod rozwiązania oraz zrzuty ekranu pokazujące wyniki, (dołącz kod rozwiązania w formie tekstowej/źródłowej)

Zwróć uwagę na formatowanie kodu

---

### Oprogramowanie - co jest potrzebne?

Do wykonania ćwiczenia potrzebne jest następujące oprogramowanie:

- MS SQL Server - wersja 2019, 2022, 2025
- PostgreSQL - wersja 15/16/17/18
- SQLite
- Narzędzia do komunikacji z bazą danych
  - SSMS - Microsoft SQL Managment Studio
  - DDataGrip lub DBeaver
- Przykładowa baza Northwind
  - W wersji dla każdego z wymienionych serwerów

Oprogramowanie dostępne jest na przygotowanej maszynie wirtualnej

### Dokumentacja/Literatura

- Kathi Kellenberger, Clayton Groom, Ed Pollack, Expert T-SQL Window Functions in SQL Server 2019, Apr 2019

- W razie potrzeby - opis ikonek używanych w graficznej prezentacji planu zapytania w SSMS jest tutaj:
    - <https://docs.microsoft.com/en-us/sql/relational-databases/showplan-logical-and-physical-operators-reference>

## Przygotowanie

Uruchom SSMS - Skonfiguruj połączenie z bazą Northwind na lokalnym serwerze MS SQL

Uruchom DataGrip (lub Dbeaver)

- Skonfiguruj połączenia z bazą Northwind3
    - na lokalnym serwerze MS SQL
    - na lokalnym serwerze PostgreSQL
    - z lokalną bazą SQLite
- 

## Zadanie 1 - obserwacja

Wykonaj i porównaj wyniki następujących poleceń.

```
select avg(unitprice) avgprice
from products p;
```

```
select avg(unitprice) over () as avgprice
from products p;
```

```
select categoryid, avg(unitprice) avgprice
from products p
group by categoryid
```

```
select avg(unitprice) over (partition by categoryid) as avgprice
from products p;
```

Jaka jest są podobieństwa, jakie różnice pomiędzy grupowaniem danych a działaniem funkcji okna?

---

Wyniki:

```
select avg(unitprice) avgprice
from products p;
```

=> jeden wiersz, globalna średnia równa ~28.834

===

```
select avg(unitprice) over () as avgprice
from products p;
```

=> 77 wierszy, globalna średnia równa ~28.834 "doklejona" do każdego wiersza (okno zdefiniowane jako wszystkie wiersze)

===

```
select categoryid, avg(unitprice) avgprice
from products p
group by categoryid;
```

=> 8 wierszy, dla każdego categoryid mamy średnią dla danej kategorii, oryginalne wiersze zostały zredukowane do agregatów

===

```
select avg(unitprice) over (partition by categoryid) as avgprice
from products p;
```

=> 77 wierszy, do każdego wiersza doklejona jest średnia z danej kategorii (categoryid)

===

```
select p.productid, p.ProductName, p.unitprice,
       (select avg(unitprice) from products) as avgprice
from products p
where productid < 10;
```

=> 9 wierszy, do każdego doklejona jest globalna średnia (bo mamy podzapytanie, w którym nie obowiązuje filtr productid < 10) równa ~28.834

```
select p.productid, p.ProductName, p.unitprice,
       avg(unitprice) over () as avgprice
from products p
where productid < 10;
```

=> 9 wierszy, do każdego doklejona jest średnia z tych 9. wierszy (filtr obowiązuje wewnątrz okna) równa ~ 31.372

---

## Zadanie 2 - obserwacja

Wykonaj i porównaj wyniki następujących poleceń.

--1)

```
select p.productid, p.ProductName, p.unitprice,
       (select avg(unitprice) from products) as avgprice
from products p
where productid < 10
```

--2)

```
select p.productid, p.ProductName, p.unitprice,
       avg(unitprice) over () as avgprice
from products p
where productid < 10
```

Jaka jest różnica? Czego dotyczy warunek w każdym z przypadków?

Napisz polecenie równoważne

- 1. z wykorzystaniem funkcji okna.
  - 2. z wykorzystaniem podzapytania
- 

Wyniki:

Podobnie jak w zadanie 1. - w przypadku pierwszego zapytania średnia uwzględnia wszystkie rekordy (avgprice to wynik podzapytania, w którym warunek where productid < 10 już nie obowiązuje), w przypadku drugiego zapytania warunek ten jest uwzględniany, a funkcja okna bierze średnią wyłącznie z tych odfiltrowanych 9. wierszy. W obu przypadkach wartości średniej są doklejane do wszystkich wierszy.

```
--1-with-window)
select productid, productname, unitprice, avgprice
from (
  select p.productid, p.productname, p.unitprice,
         avg(unitprice) over () as avgprice
  from products p
) sub
where productid < 10;
```

```
--2-with-subquery)
select p.productid, p.ProductName, p.unitprice,
       (select avg(unitprice) from products where productid < 10)
from products p
where productid < 10
```

---

### Zadanie 3

Baza: Northwind, tabela: products

Napisz polecenie, które zwraca: id produktu, nazwę produktu, cenę produktu, średnią cenę wszystkich produktów.

Napisz polecenie z wykorzystaniem z wykorzystaniem podzapytania, join'a oraz funkcji okna. Porównaj czasy oraz plany wykonania zapytań.

Przetestuj działanie w różnych SZBD (MS SQL Server, PostgreSQL, SQLite)

W SSMS włącz dwie opcje: Include Actual Execution Plan oraz Include Live Query Statistics

W DataGrip użyj opcji Explain Plan/Explain Analyze

Figure 1: w:700

---

Wyniki:

Różnice w czasie wykonania zapytania są marginalne ze względu na rozmiar tabeli products (77 wierszy) - w rezultacie nie ma sensu porównywanie czasu wykonania zapytań.

```
--subquery
select p.productid, p.productname, p.unitprice,
       (select avg(unitprice) from products) as avgprice
from products p;
```

| ↳ Full Scan              | table: (subquery-2); | SCAN (subquery-2)       |

## Zadanie 4

Baza: Northwind, tabela products

Napisz polecenie, które zwraca: id produktu, nazwę produktu, cenę produktu, średnią cenę produktów w kategorii, do której należy dany produkt. Wyświetl tylko pozycje (produkty) których cena jest większa niż średnia cena.

Napisz polecenie z wykorzystaniem podzapytania, join'a oraz funkcji okna. Porównaj zapytania. Porównaj czasy oraz plany wykonania zapytań.

Przetestuj działanie w różnych SZBD (MS SQL Server, PostgreSQL, SQLite)

Wyniki: W MSSQL plan wykonania jest dostosowany przez optymalizator i podmieniony na najbardziej optymalny (totalTime 0.0). W przypadku Postgresql i SQLite plan wykonania jest zgodny z napisanym zapytaniem.

```
--subquery
select p1.ProductID, p1.ProductName, p1.UnitPrice, (
    select avg(p2.unitprice)
    from products p2
    where p1.categoryid = p2.categoryid
) as AvgCategoryPrice
from Products p1
where p1.UnitPrice > (select avg(p3.UnitPrice) from Products p3 where
p1.CategoryID = p3.CategoryID)
order by p1.ProductID;
```

### Postgres:

| Operation              | Params           | Rows | Actual Rows | Total Cost | Actual Total Time | Startup Cost | Actual Startup Time |
|------------------------|------------------|------|-------------|------------|-------------------|--------------|---------------------|

## Zadanie 5

Oryginalna baza Northwind jest bardzo mała. Warto zaobserwować działanie na nieco większym zbiorze danych.

Baza Northwind3 zawiera dodatkową tabelę product\_history

- 2,2 mln wierszy

Bazę Northwind3 można pobrać z moodle (zakładka - Backupy baz danych)

Można też wygenerować tabelę product\_history przy pomocy skryptu

Skrypt dla SQL Sserver

Stwórz tabelę o następującej strukturze:

```

create table product_history(
    id int identity(1,1) not null,
    productid int,
    productname varchar(40) not null,
    supplierid int null,
    categoryid int null,
    quantityperunit varchar(20) null,
    unitprice decimal(10,2) null,
    quantity int,
    value decimal(10,2),
    date date,
    constraint pk_product_history primary key clustered
        (id asc )
)

```

Wygeneruj przykładowe dane:

Dla 30000 iteracji, tabela będzie zawierała nieco ponad 2mln wierszy (dostostu ograniczenie do możliwości swojego komputera)

Skrypt dla SQL Sserver

```

declare @i int
set @i = 1
while @i <= 30000
begin
    insert product_history
    select productid, ProductName, SupplierID, CategoryID,
        QuantityPerUnit, round(RAND()*unitprice + 10,2),
        cast(RAND() * productid + 10 as int), 0,
        dateadd(day, @i, '1940-01-01')
    from products
    set @i = @i + 1;
end;

update product_history
set value = unitprice * quantity
where 1=1;

```

Skrypt dla Postgresql

```
create table product_history(  
    id int generated always as identity not null  
        constraint pkproduct_history  
            primary key,  
    productid int,  
    productname varchar(40) not null,  
    supplierid int null,  
    categoryid int null,  
    quantityperunit varchar(20) null,  
    unitprice decimal(10,2) null,  
    quantity int,  
    value decimal(10,2),  
    date date  
);
```

Wygeneruj przykładowe dane:

Skrypt dla Postgresql

```
do $$  
begin  
    for cnt in 1..30000 loop  
        insert into product_history(productid, productname, supplierid,  
            categoryid, quantityperunit,  
            unitprice, quantity, value, date)  
        select productid, productname, supplierid, categoryid,  
            quantityperunit,  
            round((random()*unitprice + 10)::numeric,2),  
            cast(random() * productid + 10 as int), 0,  
            cast('1940-01-01' as date) + cnt  
        from products;  
    end loop;  
end; $$;  
  
update product_history  
set value = unitprice * quantity  
where 1=1;
```

Wykonaj polecenia: select count(\*) from product\_history, potwierdzające wykonanie zadania

---

Wyniki:

```
select count(*) from product_history;
```

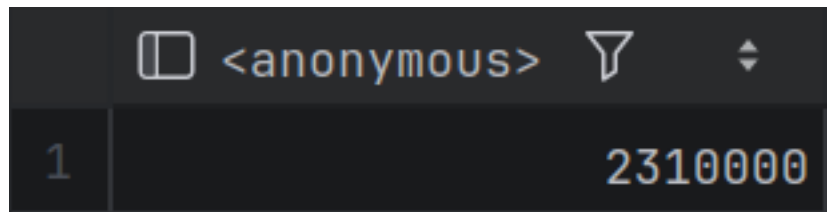

Postgres:

|   | count   |
|---|---------|
| 1 | 2310000 |

Figure 2: alt text

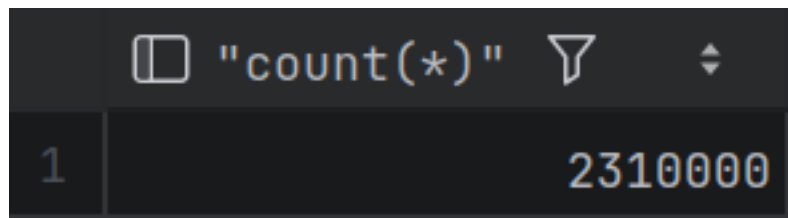

MSSQL:

|   | <anonymous> |
|---|-------------|
| 1 | 2310000     |

Figure 3: alt text

SQLite:

|   | "count(*)" |
|---|------------|
| 1 | 2310000    |

Figure 4: alt text

## Zadanie 6

Baza: Northwind, tabela product\_history

Napisz polecenie, które zwraca: id pozycji, id produktu, nazwę produktu, id\_kategorii, cenę produktu, średnią cenę produktów w kategorii do której należy dany produkt. Wyświetl tylko pozycje (produkty) których cena jest większa niż średnia cena.

W przypadku długiego czasu wykonania ogranicz zbiór wynikowy do kilkuset/kilku tysięcy wierszy pomocna może być konstrukcja with

```
with t as (  
  
....  
)  
select * from t  
where id between ....
```

Napisz polecenie z wykorzystaniem podzapytania, join'a oraz funkcji okna. Porównaj zapytania. Porównaj czasy oraz plany wykonania zapytań.

Przetestuj działanie w różnych SZBD (MS SQL Server, PostgreSQL, SQLite)

---

Wyniki: Z podzapytaniem tylko MSSQL poradził sobie w skończonym czasie (457ms, 45ms dla ograniczonego zbioru), prawdopodobnie przez paralelizm. PostgreSQL i SQLite wypadły znacznie gorzej ~1 minuta na ograniczonym zbiorze, a dla pełnego zbioru zapytanie nie zostało ukończony w rozsądnym czasie. Przy joinie wyniki wyniosły odpowiednio MSSQL 458ms, PostgreSQL 1s, SQLite 1s. Przy funkcji okna MSSQL znów był najszybszy ~500ms, PostgreSQL 1.6s, SQLite 2s.

DataGrip wskazał, że w przypadku MSSQL warto dodać indeks na kolumnie categoryid w tabeli product\_history.

```
--subquery  
select p1.id, p1.productid, p1.productname, p1.categoryid, p1.unitprice, (  
    select avg(p2.unitprice)  
    from product_history p2  
    where p1.categoryid = p2.categoryid  
) as AvgCategoryPrice  
from product_history p1  
where p1.unitprice > (  
    select avg(p3.unitprice)  
    from product_history p3  
    where p1.categoryid = p3.categoryid  
)  
order by p1.productid;
```
